

# Three Triangles Integer Factorization Algorithm

"Discovery consists of seeing what everybody has seen and thinking what nobody has thought."

— Albert Szent-Györgyi

## Abstract:

Factor the composite number  $C=(a+1)(a+b)$  by finding the solution to  $C=T(a)+T(a+b)-T(b-1)$  where  $T(n)$  is the nth triangular number.

## Definitions:

- $a, b :=$  natural numbers
- $T(n) := n(n+1)/2$
- $S(a, b) := T(a)+T(a+b)-T(b-1)$
- $\text{make\_even}(n) :=$  if  $n$  is odd return  $n-1$  else return  $n$

## Theorem:

For every composite number  $C=(a+1)(a+b)$  there exist three triangular numbers such that  $C=T(a)+T(a+b)-T(b-1)$ .

## Proof:

1.  $(a+1)(a+b)=T(a)+T(a+b)-T(b-1)$
2.  $a^2+ab+a+b=a(a+1)/2+(a+b)(a+b+1)/2-(b-1)b/2$
3.  $2a^2+2ab+2a+2b=a(a+1)+(a+b)(a+b+1)-(b-1)b$
4.  $2a^2+2ab+2a+2b=a^2+a+a(a+b+1)+b(a+b+1)-b^2+b$
5.  $2a^2+2ab+2a+2b=a^2+a+a^2+ab+a+ba+b^2+b-b^2+b$
6.  $2a^2+2ab+2a+2b=2a^2+2ab+2a+2b$
7.  $0=0$

## Theorem:

For every natural number  $a \geq 2$  and  $b > 1$  it holds that  $S(a, b) > S(a-2, b+2)$ .

## Proof:

1.  $S(a, b) > S(a-2, b+2)$
2.  $(a+1)(a+b) > (a+1-2)(a-2+b+2)$
3.  $a^2+a+b > (a-1)(a+b)$
4.  $a^2+a+b > a^2-(a+b)$
5.  $a+b > -(a+b)$
6.  $1 > -1(a+b) > 0$  since  $a \geq 2$  and  $b > 1$

## Theorem:

For every natural number  $a, b > 0$  it holds that  $S(a, b) < S(a, b+\max(1, \text{ceil}((C-S(a, b))/(a+1))))$ .

## Proof:

1.  $S(a, b) < S(a, b+\max(1, \text{ceil}((C-S(a, b))/(a+1))))$
2.  $(a+1)(a+b) < (a+1)(a+b+\max(1, \text{ceil}((C-S(a, b))/(a+1))))$
3.  $a+b < a+b+\max(1, \text{ceil}((C-S(a, b))/(a+1)))$
4.  $0 < \max(1, \text{ceil}((C-S(a, b))/(a+1)))$
5.  $0 < 1$

## Algorithm:

input:  $C \Rightarrow$  integer greater than 4

output: found factors, or 1 and  $C$  if  $C$  is a prime number

1. let  $a = \text{make\_even}(\text{floor}(\text{sqrt}(C)))$
2. let  $b = 1$
3. if  $S(a, b) > C$  then  $a=a-1, b=b+1$

4. if  $S(a, b) < C$  then  $b = b + \max(1, \text{ceil}((C - S(a, b)) / (a + 1)))$
5. if  $S(a, b) == C$  then exit: found factors  $(a + 1)$  and  $(a + b)$
6. if  $a == 0$  then exit:  $C$  is a prime number
7. goto step 3.

## Examples

### Factor 51

1.  $S(6, 1) = 49 \Rightarrow b = b + \max(1, \text{ceil}(2 / 7))$
2.  $S(6, 2) = 56 \Rightarrow a = a - 2, b = b + 2$
3.  $S(4, 4) = 40 \Rightarrow b = b + \max(1, \text{ceil}(11 / 5))$
4.  $S(4, 7) = 55 \Rightarrow a = a - 2, b = b + 2$
5.  $S(2, 9) = 33 \Rightarrow b = b + \max(1, \text{ceil}(18 / 3))$
6.  $S(2, 15) = 51 \Rightarrow 51 = 3 * 17$

### Factor 23

1.  $S(2, 1) = 9 \Rightarrow b = b + \max(1, \text{ceil}(14 / 3))$
2.  $S(2, 6) = 24 \Rightarrow a = a - 2, b = b + 2$
3.  $a = 0 \Rightarrow 23 = 1 * 23$

### factor 221

1.  $S(12, 1) = 169 \Rightarrow b = b + \max(1, \text{ceil}(52 / 13))$
2.  $S(12, 5) = 221 \Rightarrow 221 = 13 * 17$

## Conclusion

To my knowledge this is not based on any existing solutions. I do not claim it to be efficient or useful, I'm only concerned with its correctness and completeness. One potential benefit I see is the reduced magnitude of dividends used in divisions. Hope it inspires some ideas.
